## Where the $1^{\text {st }}$ Cycle ends tells us how the Image is Filled In

Finding $E$. If the first cycle ends at the top, the image is complete. In all other circumstances, there will be multiple cycles to complete the circuit (or image). There are $\boldsymbol{C}$ lines per cycle, and each line is created by counting out $\boldsymbol{P}$ subdivisions on the vertex frame. But note that a polygonal vertex occurs every $\boldsymbol{S}$ subdivisions on the vertex frame and, by construction, this point is $J$ polygonal vertices away from the 0 , the top of the parent polygon. Putting all of this together, we see that the endpoint of the first cycle, $\mathbf{E}$, is:

$$
\boldsymbol{E}=\operatorname{MOD}\left(\frac{\boldsymbol{C} * \boldsymbol{P}}{\boldsymbol{S}} * J, \boldsymbol{n}\right) \text { where MOD is the remainder upon division by } \boldsymbol{n} .
$$

The image will appear to add polygonal vertices to the image in a $\circlearrowright$ (clockwise) direction if $\boldsymbol{E}<\boldsymbol{n} / 2$ because the $2^{\text {nd }}$ endpoint will be at $2 \boldsymbol{E}<\boldsymbol{n}$.

If $\boldsymbol{E}>\boldsymbol{n} / 2$, the polygonal vertices appear to be added to the image in a $\mathcal{U}$ (counterclockwise) direction because $\operatorname{MOD}(2 E, n)<E$.

An Example: Consider two ways of drawing the image to the right. Quite clearly, $\boldsymbol{S}=3$ and $\boldsymbol{n}=4$. $\boldsymbol{J}$ can be either 1 or 3 , let $\boldsymbol{J}=1$. The first cycle must start at the top so the end of the first segment in the cycle is the last subdivision before vertex 2 or the first subdivision after vertex 2 on the vertex frame. Simple counting suggests that $\boldsymbol{P}=5$ or $\boldsymbol{P}=7$ and $\boldsymbol{C}=3$.

$\boldsymbol{P}=5$ : Then $\boldsymbol{E}=\operatorname{MOD}\left(3^{*} 5 / 3,4\right)=1$ and polygonal vertices are added in a $\cup$ direction from 1 to 2 to 3 to $4 \& 0$.
$\boldsymbol{P}=7$ : Then $\boldsymbol{E}=\operatorname{MOD}\left(3^{*} 7 / 3,4\right)=3$ and polygonal vertices are added in a $\mathcal{U}$ direction from 3 to 2 to 1 to $4 \& 0$.
Finally, if $\boldsymbol{E}=\boldsymbol{n} / 2$ the image will have two and only two cycles which are mirror images of one another. This occurs because the second cycle ends at the top of the parent polygon: $0=\operatorname{MOD}(2 E, n)$ if $E=n / 2$. The hexagonal image to the right has the same $S$, $\boldsymbol{n}$, and $\boldsymbol{J}$ as above but now $\boldsymbol{P}=2$ or $\boldsymbol{P}=10$.
$\boldsymbol{P}=2$ : Then $\boldsymbol{E}=\operatorname{MOD}\left(3^{*} 2 / 3,4\right)=2$ and the $1^{\text {st }}$ cycle is the right half of the image.
$\boldsymbol{P}=10$ : Then $\boldsymbol{E}=\operatorname{MOD}\left(3^{*} 10 / 3,4\right)=2$ and the $1^{\text {st }}$ cycle is the left half of the image.
In both instances, the second cycle completes the image.
How $\boldsymbol{E}$ tells us how the image is filled in. The size of $\boldsymbol{E}$ relative to the number of cycles
 in the image, $\boldsymbol{M}$, tells us how many times around the parent polygon vertices the drawing must lay down cycles to fill in the image. For example, this image has $\boldsymbol{E}=3$ with 29 cycles and $\boldsymbol{n}=29$ so it takes $3 \boldsymbol{x}$-around to fill in vertices 1 and 2 .
Click Toggle Drawing: https://www.playingwithpolygons.com?vertex=29\&subdivisions=12\&points=224\&jumps=13.
By contrast, this $\boldsymbol{E}=4$ image is a $2 x$-around image since the number of cycles, $\boldsymbol{M}=15$, so only half the vertices are points on the image: https://www.playingwithpolygons.com?vertex=30\&subdivisions=3\&points=58\&jumps=13 .

More generally, the number of times around the parent polygon vertices one must travel to fill in the image, $\boldsymbol{T}$, is given by an equation that depends on whether those additions are counter-clockwise ( $\boldsymbol{E}>\boldsymbol{n} / 2$ ) or clockwise ( $\boldsymbol{E}<\boldsymbol{n} / 2$ ):

Times around to fill in the image, $T=\operatorname{IF}(E>n / 2,(n-E) /(n / M), E /(n / M))$.
$1 x$-around images. If $\boldsymbol{T}=1$, then the image is created in a series 1 used-vertex changes around the parent polygon. This may involve a large number of rotations about the vertex frame, but the cycle moves one used-vertex at a time. Additionally, if $\boldsymbol{n}=\boldsymbol{M}$, the images is drawn 1 vertex at a time. The way such images are drawn can be quite dramatic:

U because $\boldsymbol{E}=1: \quad$ https://www.playingwithpolygons.com?vertex=30\&subdivisions=11\&points=127\&jumps=13
$\boldsymbol{J}$ because $\boldsymbol{E}=\boldsymbol{n}-1$ :
