## Subdivision Patterns and what this implies about $\boldsymbol{S}$ and $\boldsymbol{P}$ for Centered-Point Flowers

The simplest extension of jump patterns is to simply Jump one vertex $(\boldsymbol{J}=1)$ then $\boldsymbol{I n}$ to the center, $\boldsymbol{C}$, and back Out to the same vertex. Each move like this carries with it $\boldsymbol{S}$ subdivisions so the image shown is unlike other files in that the center is explicitly included in each jump set. Each vertex of the $\boldsymbol{n}$-gon gets used twice. Given the $\boldsymbol{n}=3$ vertex frame discussed in the Jumps Primer, this creates the following subdivision endpoints (noted beneath the vertex and center jumps):

## 0 to 1 to $\boldsymbol{C}$ to 1 to 2 to $\boldsymbol{C}$ to 2 to 3 to $\boldsymbol{C}$ to 3 <br> $S \quad 2 S \quad 3 S \quad 4 S \quad 5 S \quad 6 S \quad 7 S \quad 8 S \quad 9 S$

Because of the "Jump, In, Out" pattern, each new vertex involves three moves. Notice in particular that the following is true about the multiple, $\boldsymbol{m}$, in front of $\boldsymbol{S}$ in each case:

Jump If this is the first time vertex $\boldsymbol{v}$ is used, then $\boldsymbol{m}=3 \boldsymbol{v}-2$ ( $\boldsymbol{m}=1$ if $\boldsymbol{v}=1, \boldsymbol{m}=4$ if $\boldsymbol{v}=2$, and $\boldsymbol{m}=7$ if $\boldsymbol{v}=3$ ).
In The move into the center is always of the form: $\boldsymbol{m}=3 \boldsymbol{v}-1$ ( $\boldsymbol{m}=2$ if $\boldsymbol{v}=1, \boldsymbol{m}=5$ if $\boldsymbol{v}=2$, and $\boldsymbol{m}=8$ if $\boldsymbol{v}=3$ ).
Out The move back out from the center to $\boldsymbol{v}$ is of the form: $\boldsymbol{m}=3 \boldsymbol{v}$ ( $\boldsymbol{m}=3$ if $\boldsymbol{v}=1, \boldsymbol{m}=6$ if $\boldsymbol{v}=2$, and $\boldsymbol{m}=9$ if $\boldsymbol{v}=3$ ).
This same pattern works for values $\boldsymbol{n}$ beyond $\boldsymbol{n}=3$, for each vertex $\boldsymbol{v}$ of the $\boldsymbol{n}$-gon, $1 \leq \boldsymbol{v} \leq \boldsymbol{n}$, as we see for $\boldsymbol{n}=5$ below.

These five "pentagrams with attitude" based on $\boldsymbol{n}=5$ and $\boldsymbol{S}=4$ are each annotated with multiple values $\boldsymbol{m}$ noted above (together with $\boldsymbol{P} / \boldsymbol{S}$ which tells us where the first line lands relative to these multiples of $\boldsymbol{S}$ vertices). Each is more pentagram like than pentagon like because $4 \leq P / S<7.5=3 n / 2$ (half-way around). You should be able to see where the first line ends in each image. Remember that $\boldsymbol{m}=5$ and 8 are at the center so the top middle $5 \frac{1}{4}$ is $1 / 4^{\text {th }}$ of the way out from the center 5 to $\boldsymbol{m}=6$ at vertex 2 (and the top left first 4 lines in terms of $\boldsymbol{m}$ are 4-8-12-1 since 16-15=1). The top 3 have fewer lines because SCF >1. The bottom right is a porcupine ( $\boldsymbol{P}=31$ is the same image and $\boldsymbol{P}=30$ is a single line).
